

# **Assessment of effects of methane inhibitors in ruminants**

---

**Peter Lebzien and Gerhard Flachowsky**

**Institute of Animal Nutrition,  
Friedrich-Loeffler-Institute (FLI),  
Federal Research Institute for Animal Health,  
Braunschweig  
Germany  
[peter.lebzien@fli.bund.de](mailto:peter.lebzien@fli.bund.de)**

## Some headings in the German press

---

- **“Eating beef impairs the climate”**
- **“Will the “waste gas tax” for cows come?”**
- **“Belching cows impairs our climate”**

# Factors affecting ruminal methane production

---

- **Feeding level (DMI, % live weight)/ Mean retention time in the rumen**
- **Frequency of feeding**
- **Chemical composition of the ration (amount and type of fat and carbohydrate)**
- **Proportion of concentrate (ruminal pH)**
- **Degradation-rate of the feedstuffs**

## Influence of feeding level on $Y'_m$ (Sauvant and Giger-Reverdin 2007)

$Y'_m$  = gross energy in methane (% of gross energy intake)

# Influence of dietary proportion of concentrate on $Y'_m$ (Sauvant and Giger-Reverdin 2007)

$Y'_m$  = gross energy in methane (% of gross energy intake)

## Some feed additives tested for reducing methane emissions

Additive	Effect on CH <sub>4</sub>	Questions, problems, risks
Halogenated methane analogues	↓	<ul style="list-style-type: none"> <li>• Potentially toxic</li> <li>• Possible transfer to edible animal products</li> <li>• Only transient effects</li> <li>• Too expensive</li> <li>• Not authorised in Europe</li> </ul>
Ionophores (e. g. monensin)	↓	<ul style="list-style-type: none"> <li>• Not authorised in Europe</li> </ul>
Propionate enhancers (malate, fumarate)	(↓) - ↓↓	<ul style="list-style-type: none"> <li>• Rumen pH ↓ (acidosis)</li> <li>• DMI ↓</li> <li>• Onerous and expensive (about 2 kg for -10 % CH<sub>4</sub>)</li> <li>• Long term <i>in vivo</i> experiments are needed</li> </ul>
Lipids, some fatty acids	Depends on the type and amount	<ul style="list-style-type: none"> <li>• Too high amounts depress fibre fermentation</li> <li>• Effects on fatty acid composition in animal products has to be considered</li> <li>• Further research is needed</li> </ul>
Yeasts	In vitro: (↓) In vivo: ?	<ul style="list-style-type: none"> <li>• Validation of specific strains <i>in vivo</i> is needed</li> </ul>
Saponine, Tannine	Depends on the kind of plant	<ul style="list-style-type: none"> <li>• A lot of different chemical compounds (-mainly from tropical plants)</li> <li>• Optimal dose ?</li> <li>• Can be negative for animal health, digestibility and feed intake</li> <li>• Long term <i>in vivo</i> experiments are needed</li> </ul>
Plant extracts	Depends on the kind of plant	<ul style="list-style-type: none"> <li>• Long term <i>in vivo</i> experiments are lacking</li> </ul>

## Relationship between methane produced *in vivo* and *in vitro* from a range of diets (Moss and Givens 1997)

## Influence of fumaric acid and encapsulated fumaric acid on methane formation *in vivo* and *in vitro* (% of control, Wallace et al. 2006)

## Proposal for three stages for assessing the CH<sub>4</sub> inhibition potential of feed additives in ruminants

1. ***In vitro*** screening of various substances (if necessary with different rations)
2. ***In vivo*** experiments in target animals
  - a. **Short term** (28 - 56 d) with the most efficient substances on their effect on:
    - acceptance
    - feed intake
    - rumen fermentation incl. CH<sub>4</sub>-production
  - b. **Long term** (total lactation/growing/fattening period) recording
    - animal performance (feed intake, yields, feed conversion)
    - health
    - quality/safety of milk/meat
    - CH<sub>4</sub>-production
    - parameters of rumen fermentation during the experiment (adaptation of microbial population?)
