# Comparison of ultrasound carcass traits in young beef bulls of three breeds

**Sándor Harangi – Béla Béri**

University of Debrecen

Centre for Agricultural- and Engineering

Institute of Animal Husbandry

# Introduction

- **Considerable changes in beef cattle sector - quality-based market:** demands of excellent quality, uniform end-product ➡ improve bulls in carcass traits
- **Selection of stock animals on the basis of carcass traits:**

## **I. with the evaluation of progenies' carcasses**

Progeny testing: labourious, expensive process

average time period to prove a sire for carcass merit is 3 to 5 years

## **II. with the use of real-time ultrasound (RTU):**

- a noninvasive method for estimating carcass traits on live animals
- a quick, least expensive, accurate and precise method to obtain live-animal measures of body composition

Progeny testing: much easier and with less costs

- **Advantages of using scan data:**
  - additional information about carcass traits of that animal or its progeny
  - identifying sires or bloodlines that are superior or inferior
- **Use of ultrasound technique:** in some countries used widely in the evaluation of young bulls participating in self- or progeny performance test
- **Self-performance test in Hungary:** growing capacity, growth rate and phenotype of young bulls are measured

# Aims

***The main goals of our examination were to assess:***

- how does the ultrasound parameters of three beef breeds change at the beginning and at the end of SPT
- how does the ribeye area and subcutaneous fat thickness increase during the self performance test
- what relationship exist between the ultrasound parameters at the beginning and at the end of SPT

# Materials and methods

- Young beef bulls perform in self-performance test (SPT) made on farm
- Subcutaneous fat depth and ribeye area were measured at the beginning and at the end of SPT

**Hungarian Simmental**  
(n=19)

**Charolais**  
(n=16)

**Limousin**  
(n=11)

- **Housing:** animals were kept in small groups, on deep litter in barn with paddock
- **Feeding:** During the testing period the animals were fed on silage, grass hay and concentrate on the ration of 100 kg live weight / 1 kg concentrate

# Ultrasound devices

## Ultrasound machine:

*Falco 100 real-time scanner*

## Transducer:

*ASP - 3,5 MHz, 18 cm*

## Measurement depth:

- *Ribeye area : 23 cm*
- *Subcutaneous rump fat depth (P8): 5 cm*

## Image capturing, storing and analyzing:

- *portable PC*
- *Ultrasound Engineer 3.0*

# Ribeye area – REA

Difference is significant on \* $P < 0.05$  level, on \*\* $P < 0.01$  level

# Implications

- In Hungary it would be necessary to utilize ultrasound carcass data in beef cattle genetic improvement programs. With our examination we would like to call the attention to this fact.
- Ultrasound measurements are suitable for selecting superior bull calves which can be entered in the self performance test on farm or on a test station.
- With RTU technique differences between young bulls in muscling and subcutaneous fat deposition can be revealed.
- In possession of scan data it is possible to identify sires that are superior for a particular trait of interest.

***Thank you for your attention!***
